

Disclaimer

The following report(s) provides findings from an FDA-initiated query using Sentinel. While Sentinel queries may be undertaken to assess potential medical product safety risks, they may also be initiated for various other reasons. Some examples include determining a rate or count of an identified health outcome of interest, examining medical product use, exploring the feasibility of future, more detailed analyses within Sentinel, and seeking to better understand Sentinel capabilities.

Data obtained through Sentinel are intended to complement other types of evidence such as preclinical studies, clinical trials, postmarket studies, and adverse event reports, all of which are used by FDA to inform regulatory decisions regarding medical product safety. The information contained in this report is provided as part of FDA's commitment to place knowledge acquired from Sentinel in the public domain as soon as possible. Any public health actions taken by FDA regarding products involved in Sentinel queries will continue to be communicated through existing channels.

FDA wants to emphasize that the fact that FDA has initiated a query involving a medical product and is reporting findings related to that query does not mean that FDA is suggesting health care practitioners should change their prescribing practices for the medical product or that patients taking the medical product should stop using it. Patients who have questions about the use of an identified medical product should contact their health care practitioners.

The following report contains a description of the request, request specifications, and results from the modular program run(s).

Overview for Request cder_mpl1p_wp091_nsdp_v01

Request ID: cder_mpl1p_wp091_nsdp_v01

Request Description: In this report, we described counts and characteristics of mothers linked or unlinked to an infant record using the Sentinel Common Data Model (SCDM) Mother-Infant Linkage (MIL) Table with livebirth deliveries¹ in the Sentinel Distributed Database (SDD). Additionally, we included data on mothers with both live and non-live births identified through a pregnancy algorithm²⁻⁸—using codes rather than the MIL table. This is a rerun of a prior query (cderr_mpl1r_wp164)⁹ from 2020 to incorporate additional data and cohorts. Besides the inclusion of additional data from 2020 to 2024, this rerun includes additional data related to COVID-19 status and included Medicaid data which had been added to the MIL Table in 2022. Additionally, this rerun differs from the prior query with the addition of mothers with live and non-live birth deliveries identified through a pregnancy algorithm rather than relying on the MIL Table. We also included cohorts with varying enrollment requirements based on the estimated pregnancy episode start (90 days prior, at the estimated pregnancy episode start, or 98 days after) to assess how different enrollment criteria affect the capture of females. This is Report 1 of 3. This report includes data from all six Sentinel Data Partners that populated the MIL table. Report 2 of 3 includes only Medicaid data that populated the MIL table. Data from the remaining five non-Medicaid data partners is included in Report 3 of 3.

Sentinel Routine Querying Module: Cohort Identification and Descriptive Analysis (CIDA) module, version 13.1.2, with custom programming.

Data Source: We distributed this request to the 6 Sentinel Data Partners that populate the MIL table on September 10, 2024. For this report the study period included data from January 1, 2000 through January 31, 2024. Please see Appendix A for a list of dates of available data for each Data Partner.

Study Design: This is a Type 4 analysis in the Query Request Package (QRP) documentation with custom programming to assess baseline and pregnancy characteristics, as well as the use of medical products before and during pregnancy. The analysis includes females aged 10 to 54 years with: a) singleton deliveries identified through MIL tables linked to a live-born infant, b) singleton deliveries identified through MIL tables unlinked to a live-born infant, c) all singleton deliveries identified through MIL tables (linked or unlinked to a live-born infant), d) live-birth deliveries identified through a claims-based pregnancy algorithm²⁻⁸ (not necessarily using MIL tables), and e) non-live birth deliveries identified through a claims-based pregnancy algorithm²⁻⁸. There are overlaps between live birth deliveries identified through MIL tables and those identified by pregnancy algorithms, as both use the same data but apply different strategies to identify deliveries. Pregnancies are captured using claims-based pregnancy-related algorithms even if they are not included in the MIL tables, which may be due to stricter enrollment criteria for deliveries in the MIL tables. Also, unlike those in the MIL tables, the live birth deliveries identified by algorithms are not restricted to singleton deliveries.

Pregnancy Episode Creation: We used a claim-based algorithm²⁻⁸ to identify pregnancies resulting in both live and non-live births (including stillbirths, spontaneous abortions, induced abortions, ectopic pregnancies, and trophoblastic disease) outcomes. The same claim-based algorithm was used to identify live birth deliveries, and the methods for calculating the duration of pregnancy episodes were consistent for mothers included in the MIL Table and those not included. The only difference is that to be eligible for inclusion in the MIL Table, live birth deliveries must meet additional criteria, such as specific enrollment requirements, as described later in the text.

This algorithm identifies the pregnancies and calculates the duration of each pregnancy episode. To identify live and non-live birth outcomes, the algorithm relies on a combination of the International Classification of Diseases, Ninth and Tenth Revisions (ICD-9-CM and ICD-10-CM) diagnosis and procedure codes found in the SCDM.

Live births can be identified based on codes or using the SCDM MIL Table. Live births are defined using an updated code list (incorporating ICD-10-CM and ICD-10 Procedure Coding System [ICD-10-PCS] codes) developed by the Medication Exposure in Pregnancy Risk Evaluation Program (MEPREP) and other Sentinel and non-Sentinel pregnancy-related projects. The algorithm also assesses the incidence of pregnancy outcomes by extracting records of co-occurring events within a ± 3 -day timeframe, ensuring the validity of these outcomes within a clinically plausible window.

Overview for Request cder_mpl1p_wp091_nsdv_v01

The MIL Table identifies live birth deliveries and matches mother patient IDs to infant patient IDs when possible. To be eligible for inclusion in the MIL Table, live birth deliveries must meet certain criteria, including occurring at least 90 days after the start of data availability, including females aged 10 to 54 years, and showing no evidence of delivery in the 180 days prior.

Additionally, females must have had 90 days of continuous medical coverage, with 45 days allowed gaps.

After identifying pregnancy outcomes, the algorithm calculates the length of each episode using a hierarchy of pregnancy markers, including diagnosis codes indicative of gestational weeks, prenatal visit codes, and trimester codes. The estimated start of the pregnancy episode, or the last menstrual period, is determined by subtracting the calculated episode length from the date of the pregnancy outcome.

Pregnancy episodes are categorized into trimesters: the first trimester spans 0 to 97 days, the second from 98 to 195 days, and the third from 196 days until the pregnancy outcome date. Also, live births are classified into categories such as preterm, early term, full term, late-term, and post-term based on the duration of the pregnancy episode. Please see Appendix B for a list of International Classification of Diseases, Ninth Revision, Clinical Modification (ICD-9-CM) and International Classification of Diseases, Tenth Revision, Clinical Modification (ICD-10-CM) codes used as index-defining codes for live birth deliveries and non-live birth deliveries in this request, and Appendix B.1 for a list of Current Procedural Terminology, Fourth Edition (CPT-4), Healthcare Common Procedure Coding System, Level II (HCPCS), International Classification of Diseases, Ninth Revision, Clinical Modification (ICD-9-CM), International Classification of Diseases, Tenth Revision, Procedural Coding System (ICD-10-PCS), and codes used as index-defining codes for non-live birth deliveries in this request.

Cohort Eligibility Criteria: The estimated pregnancy episode start is the index date. To assess the capture of females under varying enrollment requirements related to the estimated pregnancy episode start (index), we included three scenarios for cohorts with live birth deliveries (identified through MIL Tables or algorithms), each based on different start of the continuous enrollment periods with a 45-day gap allowed: 1) 90 days prior to the index date, 2) at the index date, and 3) 98 days after index. Non-live births had one scenario based on 90 days prior to index. This results in 13 total scenarios:

Singleton Live Birth Deliveries Identified Through MIL Tables:

1. Linked with continuous enrollment from 90 days prior to index (estimated pregnancy start) until pregnancy outcome.
2. Linked with continuous enrollment from the index (estimated pregnancy start) until pregnancy outcome.
3. Linked with continuous enrollment from 98 days after index (estimated pregnancy start) until pregnancy outcome.
4. Unlinked with continuous enrollment from 90 days prior to index (estimated pregnancy start) until pregnancy outcome.
5. Unlinked with continuous enrollment from the index (estimated pregnancy start) until pregnancy outcome.
6. Unlinked with continuous enrollment from 98 days after index (estimated pregnancy start) until pregnancy outcome.
7. All (linked and unlinked) with continuous enrollment from 90 days prior to index (estimated pregnancy start) until pregnancy outcome.
8. All (linked and unlinked) with continuous enrollment from index (estimated pregnancy start) until pregnancy outcome.
9. All (linked and unlinked) with continuous enrollment from 98 days after index (estimated pregnancy start) until pregnancy outcome.

Live Birth Deliveries Identified by Pregnancy Algorithm:

10. Live births with continuous enrollment from 90 days prior to index (estimated pregnancy start) until pregnancy outcome.
11. Live births with continuous enrollment from index (estimated pregnancy start) until pregnancy outcome.
12. Live births with continuous enrollment from 98 days after index until pregnancy outcome.

Non-Live Birth Deliveries Identified by Pregnancy Algorithm:

13. Non-live births with continuous enrollment from 90 days prior to index until pregnancy outcome.

Overview for Request cder_mpl1p_wp091_nsdv_v01

All cohorts included females in the following age groups, based on the mother's age at the time of pregnancy outcome: 10-19, 20-24, 25-29, 30-34, 35-39, 40-44, and 45-54 years.

Singleton deliveries were included for live births identified through MIL Tables, while the algorithm-based deliveries were not restricted to singleton deliveries. Also, linked mothers in the Mother-Infant Linkage Tables had to meet an extra criterion: the paired infant must have at least 1 day of the same coverage as specified for the mother. This requirement did not apply to unlinked deliveries or to cohorts identified by the pregnancy algorithm.

Baseline Characteristics: We assessed health services utilization in the 90 days prior to the pregnancy start date. We assessed the following pre-existing conditions in the 90 days prior to pregnancy start through 97 days after pregnancy start: psychiatric conditions (including depression, anxiety disorders, attention deficit hyperactivity disorder, personality disorders, schizophrenia and other psychotic disorders, bipolar disorder, and post-traumatic stress disorder), neurologic conditions (including epilepsy, migraines, pain conditions, multiple sclerosis, non-Alzheimer's dementia, Parkinson's disease and secondary parkinsonism, and Alzheimer's disease), pulmonary diseases (including asthma, pulmonary embolism, chronic obstructive pulmonary disease, and all-cause pneumonia), cardiovascular, metabolic, and renal conditions (including hypertension, hyperlipidemia, diabetes [Type 1 and Type 2], chronic kidney disease, obesity, overweight, acute myocardial infarction, atrial fibrillation and flutter, heart failure and non-ischemic heart disease, ischemic heart disease, and stroke or transient ischemic attack), autoimmune and immune system diseases (including rheumatoid arthritis, osteoarthritis, lupus, psoriasis or psoriatic arthritis, Crohn's disease, ulcerative colitis, acquired hypothyroidism, and hyperthyroidism), cancers (including breast cancer, colorectal cancer, cervical cancer, leukemia and lymphoma, melanoma, thyroid cancer, endometrial cancer, lung cancer, and urologic cancer), musculoskeletal diseases (including osteoporosis and hip or pelvic fractures), and other conditions (including drug abuse, tobacco use, alcohol abuse, anemia, sickle cell disease, liver disease including cirrhosis, viral hepatitis, HIV/AIDS, cataracts, glaucoma, and COVID-19 diagnosis).

In the women's entire history prior to pregnancy start we assessed: preterm delivery and evidence of other pregnancies (including live born deliveries, stillbirth, and miscarriage). In relation to pregnancy start and pregnancy outcome, we assessed the following conditions, using validated algorithms when available: cesarean delivery, gestational diabetes, pre-eclampsia/eclampsia, and gestational hypertension.

For the non-live birth cohort, the number and proportion of each type of non-live birth delivery (including ectopic pregnancy, induced abortion, spontaneous abortion, stillbirth, and trophoblastic disease) are also included in the baseline tables.

**Glossary of Terms for Analyses Using
Cohort Identification and Descriptive Analysis (CIDA) Module***

Amount Supplied - number of units (pills, tablets, vials) dispensed. Net amount per NDC per dispensing.

Blackout Period - number of days at the beginning of a treatment episode that events are to be ignored. If an event occurs during the blackout period, the episode is excluded.

Care Setting - type of medical encounter or facility where the exposure, event, or condition code was recorded. Possible care settings include: Inpatient Hospital Stay (IP), Non-Acute Institutional Stay (IS), Emergency Department (ED), Ambulatory Visit (AV), and Other Ambulatory Visit (OA). For laboratory results, possible care settings include: Emergency Department (E), Home (H), Inpatient (I), Outpatient (O), or Unknown or Missing (U). The Care Setting, along with the Principal Diagnosis Indicator (PDX), forms the Care Setting/PDX parameter.

Ambulatory Visit (AV) - includes visits at outpatient clinics, same-day surgeries, urgent care visits, and other same-day ambulatory hospital encounters, but excludes emergency department encounters.

Emergency Department (ED) - includes ED encounters that become inpatient stays (in which case inpatient stays would be a separate encounter). Excludes urgent care visits.

Inpatient Hospital Stay (IP) - includes all inpatient stays, same-day hospital discharges, hospital transfers, and acute hospital care where the discharge is after the admission date.

Non-Acute Institutional Stay (IS) - includes hospice, skilled nursing facility (SNF), rehab center, nursing home, residential, overnight non-hospital dialysis and other non-hospital stays.

Other Ambulatory Visit (OA) - includes other non overnight AV encounters such as hospice visits, home health visits, skilled nursing facility visits, other non-hospital visits, as well as telemedicine, telephone and email consultations.

Charlson/Elixhauser Combined Comorbidity Score - calculated based on comorbidities observed during a requester-defined window around the exposure episode start date (e.g., in the 183 days prior to index).

Code Days - the minimum number of times the diagnosis must be found during the evaluation period in order to fulfill the algorithm to identify the corresponding patient characteristic.

Cohort Definition (drug/exposure) - indicates how the cohort will be defined: 01: Cohort includes only the first valid treatment episode during the query period; 02: Cohort includes all valid treatment episodes during the query period; 03: Cohort includes all valid treatment episodes during the query period until an event occurs.

Computed Start Marketing Date - represents the first observed dispensing date among all valid users within a GROUP (scenario) within each Data Partner site.

Days Supplied - number of days supplied for all dispensings in qualifying treatment episodes.

Eligible Members - number of members eligible for an incident treatment episode (defined by the drug/exposure and event washout periods) with drug and medical coverage during the query period.

Enrollment Gap - number of days allowed between two consecutive enrollment periods without breaking a "continuously enrolled" sequence.

Episodes - treatment episodes; length of episode is determined by days supplied in one dispensing or consecutive dispensings bridged by the episode gap.

Episode Gap - number of days allowed between two (or more) consecutive exposures (dispensings/procedures) to be considered the same treatment episode.

Event Deduplication - specifies how events are counted by the Modular Program (MP) algorithm: 0: Counts all occurrences of a health outcome of interest (HOI) during an exposure episode; 1: de-duplicates occurrences of the same HOI code and code type on the same day; 2: de-duplicates occurrences of the same HOI group on the same day (e.g., de-duplicates at the group level).

Exposure Episode Length - number of days after exposure initiation that is considered "exposed time."

Exposure Extension Period - number of days post treatment period in which the outcomes/events are counted for a treatment episode. Extensions are added after any episode gaps have been bridged.

Lookback Period - number of days wherein a member is required to have evidence of pre-existing condition (diagnosis/procedure/drug dispensing).

Maximum Episode Duration - truncates exposure episodes after a requester-specified number of exposed days. Applied after any gaps are bridged and extension days added to the length of the exposure episode.

**Glossary of Terms for Analyses Using
Cohort Identification and Descriptive Analysis (CIDA) Module***

Member-Years - sum of all days of enrollment with medical and drug coverage in the query period preceded by an exposure washout period all divided by 365.25.

Minimum Days Supplied - specifies a minimum number of days in length of the days supplied for the episode to be considered.

Minimum Episode Duration - specifies a minimum number of days in length of the episode for it to be considered. Applied after any gaps are bridged and extension days added to the length of the exposure episode.

Monitoring Period - used to define time periods of interest for both sequential analysis and simple cohort characterization requests.

Principal Diagnosis (PDX) - diagnosis or condition established to be chiefly responsible for admission of the patient to the hospital. 'P' = principal diagnosis, 'S' = secondary diagnosis, 'X' = unspecified diagnosis, '.' = blank. Along with the Care Setting values, forms the Caresetting/PDX parameter.

Query Period - period in which the modular program looks for exposures and outcomes of interest.

Switch Evaluation Step Value - value used to differentiate evaluation step. Each switch pattern can support up to 2 evaluation steps (0 = switch pattern evaluation start; 1 = first evaluation; 2 = second evaluation).

Switch Gap Inclusion Indicator - indicator for whether gaps in treatment episodes that are included in a switch episode will be counted as part of the switch episode duration.

Switch Pattern Cohort Inclusion Date - indicates which date to use for inclusion into the switch pattern cohort of interest as well as optionally as the index date of the treatment episode initiating the switch pattern. Valid options are the product approval date, product marketing date, other requester defined date, or computed start marketing date.

Switch Pattern Cohort Inclusion Strategy - indicates how the switch pattern cohort inclusion date will be used: 01: used only as a switch cohort entry date. First treatment episode dispensing date is used as index for computing time to first switch; 02: used as switch cohort entry date and as initial switch step index date for computing time to first switch.

Treatment Episode Truncation Indicator - indicates whether the exposure episode will be truncated at the occurrence of a requester-specified code.

Washout Period (drug/exposure) - number of days a user is required to have no evidence of prior exposure (drug dispensing/procedure) and continuous drug and medical coverage prior to an incident treatment episode.

Washout Period (event/outcome) - number of days a user is required to have no evidence of a prior event (procedure/diagnosis) and continuous drug and medical coverage prior to an incident treatment episode.

Years at Risk - number of days supplied plus any episode gaps and exposure extension periods all divided by 365.25.

1 The analysis includes females with singleton deliveries identified through MIL tables linked to a live-born infant. To be included in the MIL Table, live birth deliveries must occur at least 90 days after data availability, include females aged 10 to 54 years, and show no evidence of deliveries in the 180 days prior. Additionally, females must have 90 days of continuous medical coverage, with gaps of up to 45 days. For linked mothers, the paired infant must have at least 1 day of the same coverage.

To assess capture under varying enrollment requirements related to the estimated pregnancy episode start (index), we considered three scenarios: 1) 90 days prior to the index date, 2) at the index date, and 3) 98 days after the index. This table presents results for the continuous enrollment begins at the estimated pregnancy episode.

For more details on how pregnancies are identified, please refer to the method outlined in the overview section of this report.

2 All metrics are based on total number of episodes per group, except for sex, race, and Hispanic origin which are based on total number of unique patients.

3 Value represents standard deviation where no % follows the value.

4 Race data may not be completely populated at all Data Partners; therefore, data about race may be incomplete.

5 The length of the pregnancy episode was estimated using a hierarchy of pregnancy markers. If overlapping pregnancy episodes were constructed in the same patient due to observation of multiple pregnancy markers, then the markers providing more reliable estimation of pregnancy start was selected for estimation of pregnancy start date. If no pregnancy markers were observed, then a fixed pregnancy duration was assigned by pregnancy outcome type, as described in the overview section of this report.

1 The analysis includes females with singleton deliveries identified through MIL tables linked to a live-born infant. To be included in the MIL Table, live birth deliveries must occur at least 90 days after data availability, include females aged 10 to 54 years, and show no evidence of deliveries in the 180 days prior. Additionally, females must have 90 days of continuous medical coverage, with gaps of up to 45 days. For linked mothers, the paired infant must have at least 1 day of the same coverage.

To assess capture under varying enrollment requirements related to the estimated pregnancy episode start (index), we considered three scenarios: 1) 90 days prior to the index date, 2) at the index date, and 3) 98 days after the index. This table presents results for the continuous enrollment begins at the estimated pregnancy episode.

For more details on how pregnancies are identified, please refer to the method outlined in the overview section of this report.

2 All metrics are based on total number of episodes per group, except for sex, race, and Hispanic origin which are based on total number of unique patients.

3 Value represents standard deviation where no % follows the value.

4 Race data may not be completely populated at all Data Partners; therefore, data about race may be incomplete.

5 The length of the pregnancy episode was estimated using a hierarchy of pregnancy markers. If overlapping pregnancy episodes were constructed in the same patient due to observation of multiple pregnancy markers, then the markers providing more reliable estimation of pregnancy start was selected for estimation of pregnancy start date. If no pregnancy markers were observed, then a fixed pregnancy duration was assigned by pregnancy outcome type, as described in the overview section of this report.

Mothers with Singleton Live Birth Deliveries Identified Through the Mother-Infant Linkage (MIL) Table Unlinked to a Live-Born Infant, with Continuous Enrollment of 90 Days Prior to Estimated Pregnancy Start Until Pregnancy Outcome

1 The analysis includes females with singleton deliveries identified through MIL tables unlinked to a live-born infant. To be included in the MIL Table, live birth deliveries must occur at least 90 days after data availability, include females aged 10 to 54 years, and show no evidence of deliveries in the 180 days prior. Additionally, females must have 90 days of continuous medical coverage, with gaps of up to 45 days. For unlinked mothers, there is no additional inclusion criterion beyond those specified for the mothers themselves. This differs from the linked mothers, where the paired infant must have the same coverage as specified for the mother.

To assess capture under varying enrollment requirements related to the estimated pregnancy episode start (index), we considered three scenarios: 1) 90 days prior to the index date, 2) at the index date, and 3) 98 days after the index. This table presents results for the 90 days of continuous enrollment begins before the estimated pregnancy episode start.

For more details on how pregnancies are identified, please refer to the method outlined in the overview section of this report.

2 All metrics are based on total number of episodes per group, except for sex, race, and Hispanic origin which are based on total number of unique patients.

3 Value represents standard deviation where no % follows the value.

4 Race data may not be completely populated at all Data Partners; therefore, data about race may be incomplete.

5 The length of the pregnancy episode was estimated using a hierarchy of pregnancy markers. If overlapping pregnancy episodes were constructed in the same patient due to observation of multiple pregnancy markers, then the markers providing more reliable estimation of pregnancy start was selected for estimation of pregnancy start date. If no pregnancy markers were observed, then a fixed pregnancy duration was assigned by pregnancy outcome type, as described in the overview section of this report.

1 The analysis includes females with singleton deliveries identified through MIL tables unlinked to a live-born infant. To be included in the MIL Table, live birth deliveries must occur at least 90 days after data availability, include females aged 10 to 54 years, and show no evidence of deliveries in the 180 days prior. Additionally, females must have 90 days of continuous medical coverage, with gaps of up to 45 days. For unlinked mothers, there is no additional inclusion criterion beyond those specified for the mothers themselves. This differs from the linked mothers, where the paired infant must have the same coverage as specified for the mother.

To assess capture under varying enrollment requirements related to the estimated pregnancy episode start (index), we considered three scenarios: 1) 90 days prior to the index date, 2) at the index date, and 3) 98 days after the index. This table presents results for the continuous enrollment begins at the estimated pregnancy episode.

For more details on how pregnancies are identified, please refer to the method outlined in the overview section of this report.

2 All metrics are based on total number of episodes per group, except for sex, race, and Hispanic origin which are based on total number of unique patients.

3 Value represents standard deviation where no % follows the value.

4 Race data may not be completely populated at all Data Partners; therefore, data about race may be incomplete.

5 The length of the pregnancy episode was estimated using a hierarchy of pregnancy markers. If overlapping pregnancy episodes were constructed in the same patient due to observation of multiple pregnancy markers, then the markers providing more reliable estimation of pregnancy start was selected for estimation of pregnancy start date. If no pregnancy markers were observed, then a fixed pregnancy duration was assigned by pregnancy outcome type, as described in the overview section of this report.

1 The analysis includes females with singleton deliveries identified through MIL tables unlinked to a live-born infant. To be included in the MIL Table, live birth deliveries must occur at least 90 days after data availability, include females aged 10 to 54 years, and show no evidence of deliveries in the 180 days prior. Additionally, females must have 90 days of continuous medical coverage, with gaps of up to 45 days. For unlinked mothers, there is no additional inclusion criterion beyond those specified for the mothers themselves. This differs from the linked mothers, where the paired infant must have the same coverage as specified for the mother.

To assess capture under varying enrollment requirements related to the estimated pregnancy episode start (index), we considered three scenarios: 1) 90 days prior to the index date, 2) at the index date, and 3) 98 days after the index. This table presents results for the 98 days of continuous enrollment begins after the estimated pregnancy episode start

For more details on how pregnancies are identified, please refer to the method outlined in the overview section of this report.

2 All metrics are based on total number of episodes per group, except for sex, race, and Hispanic origin which are based on total number of unique patients.

3 Value represents standard deviation where no % follows the value.

4 Race data may not be completely populated at all Data Partners; therefore, data about race may be incomplete.

5 The length of the pregnancy episode was estimated using a hierarchy of pregnancy markers. If overlapping pregnancy episodes were constructed in the same patient due to observation of multiple pregnancy markers, then the markers providing more reliable estimation of pregnancy start was selected for estimation of pregnancy start date. If no pregnancy markers were observed, then a fixed pregnancy duration was assigned by pregnancy outcome type, as described in the overview section of this report.

1 The analysis includes females with singleton deliveries identified through MIL tables linked or unlinked to a live-born infant. To be included in the MIL Table, live birth deliveries must occur at least 90 days after data availability, include females aged 10 to 54 years, and show no evidence of deliveries in the 180 days prior. Additionally, females must have 90 days of continuous medical coverage, with gaps of up to 45 days. For this cohort which includes both linked and unlinked mothers, there is no additional inclusion criterion beyond those specified for the mothers themselves. This differs from the linked mothers, where the paired infant must have the same coverage as specified for the mother.

To assess capture under varying enrollment requirements related to the estimated pregnancy episode start (index), we considered three scenarios: 1) 90 days prior to the index date, 2) at the index date, and 3) 98 days after the index. This table presents results for the 90 days of continuous enrollment begins before the estimated pregnancy episode start.

For more details on how pregnancies are identified, please refer to the method outlined in the overview section of this report.

2 All metrics are based on total number of episodes per group, except for sex, race, and Hispanic origin which are based on total number of unique patients.

3 Value represents standard deviation where no % follows the value.

4 Race data may not be completely populated at all Data Partners; therefore, data about race may be incomplete.

5 The length of the pregnancy episode was estimated using a hierarchy of pregnancy markers. If overlapping pregnancy episodes were constructed in the same patient due to observation of multiple pregnancy markers, then the markers providing more reliable estimation of pregnancy start was selected for estimation of pregnancy start date. If no pregnancy markers were observed, then a fixed pregnancy duration was assigned by pregnancy outcome type, as described in the overview section of this report.

To be included in the MIL Table, live birth deliveries must occur at least 90 days after data availability, include females aged 10 to 54 years, and show no evidence of deliveries in the 180 days prior. Additionally, females must have 90 days of continuous medical coverage, with gaps of up to 45 days. For this cohort which includes both linked and unlinked mothers, there is no additional inclusion criterion beyond those specified for the mothers themselves. This differs from the linked mothers, where the paired infant must have the same coverage as specified for the mother.

To assess capture under varying enrollment requirements related to the estimated pregnancy episode start (index), we considered three scenarios: 1) 90 days prior to the index date, 2) at the index date, and 3) 98 days after the index. This table presents results for the continuous enrollment begins at the estimated pregnancy episode.

For more details on how pregnancies are identified, please refer to the method outlined in the overview section of this report.

2 All metrics are based on total number of episodes per group, except for sex, race, and Hispanic origin which are based on total number of unique patients.

3 Value represents standard deviation where no % follows the value.

4 Race data may not be completely populated at all Data Partners; therefore, data about race may be incomplete.

5 The length of the pregnancy episode was estimated using a hierarchy of pregnancy markers. If overlapping pregnancy episodes were constructed in the same patient due to observation of multiple pregnancy markers, then the markers providing more reliable estimation of pregnancy start was selected for estimation of pregnancy start date. If no pregnancy markers were observed, then a fixed pregnancy duration was assigned by pregnancy outcome type, as described in the overview section of this report.

¹ The analysis includes females with live-birth deliveries identified through a claims-based pregnancy algorithm. There might be overlaps between linked and unlinked live birth deliveries identified through Mother-Infant Linkage (MIL) Tables and those identified by pregnancy algorithms, as both use the same data but apply different strategies to identify deliveries. Claims-based algorithms capture pregnancies even if they are not included in the MIL tables, which may have stricter enrollment criteria. Also, live birth deliveries identified by algorithms are not limited to singleton deliveries.

To assess capture under varying enrollment requirements related to the estimated pregnancy episode start (index), we considered three scenarios: 1) 90 days prior to the index date, 2) at the index date, and 3) 98 days after the index. This table presents results for the 90 days of continuous enrollment begins before the estimated pregnancy episode start.

For more details on how pregnancies are identified, please refer to the method outlined in the overview section of this report.

² All metrics are based on total number of episodes per group, except for sex, race, and Hispanic origin which are based on total number of unique patients.

³ Value represents standard deviation where no % follows the value.

⁴ Race data may not be completely populated at all Data Partners; therefore, data about race may be incomplete.

⁵ The length of the pregnancy episode was estimated using a hierarchy of pregnancy markers. If overlapping pregnancy episodes were constructed in the same patient due to observation of multiple pregnancy markers, then the markers providing more reliable estimation of pregnancy start was selected for estimation of pregnancy start date. If no pregnancy markers were observed, then a fixed pregnancy duration was assigned by pregnancy outcome type, as described in the overview section of this report.

Mothers with Live Birth Deliveries Identified Through a Claims-Based Pregnancy Algorithm, with Continuous Enrollment of 98 Days After Estimated Pregnancy Start Until Pregnancy Outcome

¹The analysis includes females with live-birth deliveries identified through a claims-based pregnancy algorithm. There might be overlaps between linked and unlinked live birth deliveries identified through Mother-Infant Linkage (MIL) Tables and those identified by pregnancy algorithms, as both use the same data but apply different strategies to identify deliveries. Claims-based algorithms capture pregnancies even if they are not included in the MIL tables, which may have stricter enrollment criteria. Also, live birth deliveries identified by algorithms are not limited to singleton deliveries.

To assess capture under varying enrollment requirements related to the estimated pregnancy episode start (index), we considered three scenarios: 1) 90 days prior to the index date, 2) at the index date, and 3) 98 days after the index. This table presents results for the 98 days of continuous enrollment begins after the estimated pregnancy episode start.

For more details on how pregnancies are identified, please refer to the method outlined in the overview section of this report.

²All metrics are based on total number of episodes per group, except for sex, race, and Hispanic origin which are based on total number of unique patients.

³Value represents standard deviation where no % follows the value.

⁴Race data may not be completely populated at all Data Partners; therefore, data about race may be incomplete.

⁵The length of the pregnancy episode was estimated using a hierarchy of pregnancy markers. If overlapping pregnancy episodes were constructed in the same patient due to observation of multiple pregnancy markers, then the markers providing more reliable estimation of pregnancy start was selected for estimation of pregnancy start date. If no pregnancy markers were observed, then a fixed pregnancy duration was assigned by pregnancy outcome type, as described in the overview section of this report.

1 The analysis includes females with non-live-birth deliveries identified through a claims-based pregnancy algorithm. Non-live births includes stillbirths, spontaneous abortions, induced abortions, ectopic pregnancies, and trophoblastic disease outcomes. The non-live births cohort had one enrollment requirement scenario: 90 days of continuous enrollment prior to the estimated pregnancy episode start until pregnancy outcome.

For more details on how pregnancies are identified, please refer to the method outlined in the overview section of this report.

2 All metrics are based on total number of episodes per group, except for sex, race, and Hispanic origin which are based on total number of unique patients.

3 Value represents standard deviation where no % follows the value.

4 Race data may not be completely populated at all Data Partners; therefore, data about race may be incomplete.

5 Pregnancy duration is not classified by term status for pregnancies ending in non-live birth outcomes.

6The length of the pregnancy episode was estimated using a hierarchy of pregnancy markers. If overlapping pregnancy episodes were constructed in the same patient due to observation of multiple pregnancy markers, then the markers providing more reliable estimation of pregnancy start was selected for estimation of pregnancy start date. If no pregnancy markers were observed, then a fixed pregnancy duration was assigned by pregnancy outcome type, as described in the overview section of this report.

1 The analysis includes females with singleton deliveries identified through MIL tables linked to a live-born infant. To be included in the MIL Table, live birth deliveries must occur at least 90 days after data availability, include females aged 10 to 54 years, and show no evidence of deliveries in the 180 days prior. Additionally, females must have 90 days of continuous medical coverage, with gaps of up to 45 days. For linked mothers, the paired infant must have at least 1 day of the same coverage.

2 Assessing medical product use in the second trimester requires a pregnancy to continue to the second trimester (i.e. pregnancy was not terminated in the first trimester); the denominator is the total number of pregnancy episodes that progress to the second trimester.

3 Assessing medical product use in the third trimester requires a pregnancy to continue to the third trimester. The denominator is the total number of pregnancy episodes that progress to the third trimester.

4 Displayed percentages represent the number of pregnancy episodes with evidence of the exposure of interest as a proportion of all pregnancy episodes.

*******Data are not presented in these cells due to a small sample size or to ensure a small cell cannot be recalculated through the cells presented.**

1 The analysis includes females with singleton deliveries identified through MIL tables unlinked to a live-born infant. To be included in the MIL Table, live birth deliveries must occur at least 90 days after data availability, include females aged 10 to 54 years, and show no evidence of deliveries in the 180 days prior. Additionally, females must have 90 days of continuous medical coverage, with gaps of up to 45 days. For unlinked mothers, there is no additional inclusion criterion beyond those specified for the mothers themselves. This differs from the linked mothers, where the paired infant must have the same coverage as specified for the mother.

2 Assessing medical product use in the second trimester requires a pregnancy to continue to the second trimester (i.e. pregnancy was not terminated in the first trimester); the denominator is the total number of pregnancy episodes that progress to the second trimester.

3 Assessing medical product use in the third trimester requires a pregnancy to continue to the third trimester. The denominator is the total number of pregnancy episodes that progress to the third trimester.

4 Displayed percentages represent the number of pregnancy episodes with evidence of the exposure of interest as a proportion of all pregnancy episodes.

*******Data are not presented in these cells due to a small sample size or to ensure a small cell cannot be recalculated through the cells presented.**

1 The analysis includes females with singleton deliveries identified through MIL tables linked or unlinked to a live-born infant. To be included in the MIL Table, live birth deliveries must occur at least 90 days after data availability, include females aged 10 to 54 years, and show no evidence of deliveries in the 180 days prior. Additionally, females must have 90 days of continuous medical coverage, with gaps of up to 45 days. For this cohort which includes both linked and unlinked mothers, there is no additional inclusion criterion beyond those specified for the mothers themselves. This differs from the linked mothers, where the paired infant must have the same coverage as specified for the mother.

2 Assessing medical product use in the second trimester requires a pregnancy to continue to the second trimester (i.e. pregnancy was not terminated in the first trimester); the denominator is the total number of pregnancy episodes that progress to the second trimester.

3 Assessing medical product use in the third trimester requires a pregnancy to continue to the third trimester. The denominator is the total number of pregnancy episodes that progress to the third trimester.

4 Displayed percentages represent the number of pregnancy episodes with evidence of the exposure of interest as a proportion of all pregnancy episodes.

*******Data are not presented in these cells due to a small sample size or to ensure a small cell cannot be recalculated through the cells presented.**

¹The analysis includes females with live-birth deliveries identified through a claims-based pregnancy algorithm.

²Assessing medical product use in the second trimester requires a pregnancy to continue to the second trimester (i.e. pregnancy was not terminated in the first trimester); the denominator is the total number of pregnancy episodes that progress to the second trimester.

³Assessing medical product use in the third trimester requires a pregnancy to continue to the third trimester. The denominator is the total number of pregnancy episodes that progress to the third trimester.

⁴Displayed percentages represent the number of pregnancy episodes with evidence of the exposure of interest as a proportion of all pregnancy episodes.

*******Data are not presented in these cells due to a small sample size or to ensure a small cell cannot be recalculated through the cells presented.**

1 The analysis includes females with non-live-birth deliveries identified through a claims-based pregnancy algorithm. Non-live births includes stillbirths, spontaneous abortions, induced abortions, ectopic pregnancies, and trophoblastic disease outcomes.

2 Assessing medical product use in the second trimester requires a pregnancy to continue to the second trimester (i.e. pregnancy was not terminated in the first trimester); the denominator is the total number of pregnancy episodes that progress to the second trimester.

3 Assessing medical product use in the third trimester requires a pregnancy to continue to the third trimester. The denominator is the total number of pregnancy episodes that progress to the third trimester.

4 Displayed percentages represent the number of pregnancy episodes with evidence of the exposure of interest as a proportion of all pregnancy episodes.

1 The analysis includes females with singleton deliveries identified through MIL tables linked to a live-born infant. To be included in the MIL Table, live birth deliveries must occur at least 90 days after data availability, include females aged 10 to 54 years, and show no evidence of deliveries in the 180 days prior. Additionally, females must have 90 days of continuous medical coverage, with gaps of up to 45 days. For linked mothers, the paired infant must have at least 1 day of the same coverage.

2 Based on the mother's age at the time of pregnancy outcome.

3 Eligible pregnancies are reflective of the number of all pregnancy episodes in each age group.

4 Any use during pregnancy is defined as medical product use during the first, second, or third trimester of the pregnancy episode. Evaluation does not include the delivery admission date.

1 The analysis includes females with singleton deliveries identified through MIL tables unlinked to a live-born infant. To be included in the MIL Table, live birth deliveries must occur at least 90 days after data availability, include females aged 10 to 54 years, and show no evidence of deliveries in the 180 days prior. Additionally, females must have 90 days of continuous medical coverage, with gaps of up to 45 days. For unlinked mothers, there is no additional inclusion criterion beyond those specified for the mothers themselves. This differs from the linked mothers, where the paired infant must have the same coverage as specified for the mother.

2 Based on the mother's age at the time of pregnancy outcome.

3 Eligible pregnancies are reflective of the number of all pregnancy episodes included in each age group.

4 Any use during pregnancy is defined as medical product use during the first, second, or third trimester of the pregnancy episode. Evaluation does not include the delivery admission date.

1 The analysis includes females with singleton deliveries identified through MIL tables linked or unlinked to a live-born infant. To be included in the MIL Table, live birth deliveries must occur at least 90 days after data availability, include females aged 10 to 54 years, and show no evidence of deliveries in the 180 days prior. Additionally, females must have 90 days of continuous medical coverage, with gaps of up to 45 days. For this cohort which includes both linked and unlinked mothers, there is no additional inclusion criterion beyond those specified for the mothers themselves. This differs from the linked mothers, where the paired infant must have the same coverage as specified for the mother.

2 Based on the mother's age at the time of pregnancy outcome.

3 Eligible pregnancies are reflective of the number of all pregnancy episodes included in each age group.

4 Any use during pregnancy is defined as medical product use during the first, second, or third trimester of the pregnancy episode. Evaluation does not include the delivery admission date.

¹The analysis includes females with live-birth deliveries identified through a claims-based pregnancy algorithm.

²Based on the mother's age at the time of pregnancy outcome.

³Eligible pregnancies are reflective of the number of all pregnancy episodes included in each age group.

⁴Any use during pregnancy is defined as medical product use during the first, second, or third trimester of the pregnancy episode. Evaluation does not include the delivery admission date.

1 The analysis includes females with non-live-birth deliveries identified through a claims-based pregnancy algorithm. Non-live births includes stillbirths, spontaneous abortions, induced abortions, ectopic pregnancies, and trophoblastic disease outcomes.

2 Based on the mother's age at the time of pregnancy outcome.

3 Eligible pregnancies are reflective of the number of all pregnancy episodes included in each age group.

4 Any use during pregnancy is defined as medical product use during the first, second, or third trimester of the pregnancy episode. Evaluation does not include the delivery admission date.

N/A: Not Applicable

¹Cohorts are formed by first evaluating enrollment and demographic requirements as well as index events among members, then evaluating index dates, pre-index history, and post-index follow-up among pregnancy episodes. Because of this, the number remaining often increases from the member- to episode-level steps.

²Pregnancy is defined as a pregnancy that resulted in a live or non-live birth identified using the method specified in the overview section of this report.

³Linked mothers in the Mother-Infant Linkage Tables must meet an additional inclusion criterion: the paired infant must have the same coverage as specified for the mother. This requirement does not apply to unlinked and all mothers cohorts.

²Caresetting/ Principal Diagnosis :

Inpatient Hospital Stay (IP*) - includes all inpatient stays, same-day hospital discharges, hospital transfers, and acute hospital care where the discharge is after the admission date. The (*) indicates restriction of codes to those observed in the inpatient setting irrespective of the principal diagnosis flag value.

Ambulatory Visit (AV) - includes visits at outpatient clinics, same-day surgeries, urgent care visits, and other same-day ambulatory hospital encounters, but excludes emergency department encounters.

Other Ambulatory Visit (OA) -- includes other non overnight AV encounters such as hospice visits, home health visits, skilled nursing facility visits, other non-hospital visits, as well as telemedicine, telephone and email consultations.

Any - inpatient hospital stay (IS), non-acute institutional stay (IS), emergency department encounters (ED), ambulatory visits (AV), or other ambulatory visits (OA)

N/A: Not Applicable
